

Name: GANALONGO ANGELO O.
Course/Section: BSIT 4-A
Instructor: TORRES JENKIELYN CORTEZ
School Year: 2026–2027

Part 1 – Create Your Course GitHub Repository

Repository Information

- **Repository Name:** cloud-computing-course
- **Description:** Repository for course activities, notes, and projects in Cloud Computing.
- **Visibility:** Public / Private
- **README File:** ✓ Included
- **License:** MIT License

Part 2 – README.md Content

Cloud Computing Course Repository

A collection of activities, outputs, and learning resources for Cloud Computing.

About This Repository

This repository contains my activities, notes, projects, and reflections for my Cloud Computing course. It serves as an organized workspace where I can keep all my course files in one place.

Repository Contents

- Class notes and summaries
- Lab activities and exercises
- Projects
- Reflection papers

Student Information

Name: Angelo Gañalongo

Course/Section: BSIT

Instructor: TORRES JENKIELYN CORTEZ

School Year: 2026–2027

Repository Structure

cloud-computing-course/

|

|— activities/ ✓

|— projects/ ✓

|— notes/ ✓

|— reflections/ ✓

| └─ cloud-concepts-reflection.md ✓

|

└─ README.md ✓

Key Concepts Covered

- Cloud Computing Basics
- Service Models (IaaS, PaaS, SaaS)
- Deployment Models (Public, Private, Hybrid, Community)
- Version Control with Git & GitHub
- Cloud Infrastructure Management

Part 3 – Reflection Paper

Cloud Concepts Reflection

1. Cloud computing has become a part of my daily life, even before I fully understood what it was. After learning about cloud concepts, I realized that many of the applications I use every day depend on cloud technology to store data and provide online services.

The three cloud services that I use regularly are Google Drive, Messenger, and Canva. I use Google Drive to save my school documents, assignments, and presentations so I can access them from any device. Messenger helps me communicate with my classmates, teachers, friends, and family through messages, voice calls, and video calls over the internet. Canva is useful for creating presentations, posters, and other school projects because my designs are automatically saved online and can be edited anytime.

Learning about cloud computing helped me understand why these applications are fast, convenient, and reliable. Instead of saving files only on my computer, cloud services keep my data online, making it easier to access, share, and back up important files. I also learned that cloud computing offers different services, such as storage, computing power, and software that users can access through the internet without installing everything on their devices.

This lesson also made me realize the importance of protecting personal information when using cloud services. Since our files and data are stored online, we should use strong passwords, enable two-factor authentication when possible, and avoid sharing sensitive information with others.

Overall, this topic gave me a better understanding of how cloud computing supports many of the applications I use every day. I believe that knowing how cloud services work will help me become a more responsible and knowledgeable IT student while preparing me for future careers that involve modern technology.

2. The three cloud services that I use regularly are **Google Drive, Messenger, and Canva. These applications have become important in my daily life because they help me with school, communication, and creative projects. After learning about cloud computing, I now understand that these services follow different cloud models that make them easy to access through the internet.**

1. Google Drive

*** **Service Model:** Software as a Service (SaaS)**

*** **Deployment Model:** Public Cloud**

Google Drive is an example of ****Software as a Service (SaaS)**** because I can use it directly from a web browser or mobile application without installing or managing the software myself. Google is responsible for maintaining the servers, storage, updates, and security. I simply log in with my Google account to upload, download, edit, and share my files. It is classified as a ****Public Cloud**** because the service is available to anyone who creates a Google account and connects to the internet.

2. Messenger

*** **Service Model:** Software as a Service (SaaS)**

*** **Deployment Model:** Public Cloud**

Messenger is also a ****SaaS**** application because it allows users to communicate using messages, voice calls, and video calls without managing any hardware or software infrastructure. Everything is handled by Meta, including the servers and system updates. It is considered a ****Public Cloud**** service because it is available online for millions of users around the world who have a Facebook or Messenger account.

3. Canva

*** **Service Model:** Software as a Service (SaaS)**

*** **Deployment Model:** Public Cloud**

Canva is another example of ****SaaS**** because it provides online design tools through a browser or mobile app. I can create presentations, posters, and other projects without installing professional design software. My work is automatically saved online, making it easy to continue editing from different devices. Canva uses the ****Public Cloud**** since its services are available to students, teachers, businesses, and anyone who registers for an account.

Conclusion

After identifying the cloud and deployment models of these services, I realized that they all belong to the ****Software as a Service (SaaS)**** model because users only need an internet connection and an account to use them. They are also classified as ****Public Cloud**** because they are accessible to the general public over the internet. Learning these concepts helped me understand how cloud computing makes technology more convenient, reliable, and accessible in everyday life, especially for communication, file storage, and school activities.

3. Version control is very important when working with cloud infrastructure because it helps keep track of every change made to files, configurations, and project code. In cloud projects, many people may work on the same application or infrastructure at the same time. Without version control, team members could accidentally overwrite each other's work, delete important files, or create conflicts that are difficult to fix. By using a version control system like Git, every change is recorded, making it easier to organize and manage a project.

Git allows developers to save different versions of their work through commits. If a mistake happens, they can return to an earlier version instead of starting the project again. This makes development safer because errors can be corrected quickly without losing important progress. Git also supports branches, which allow developers to work on new features or test changes without affecting the main project. Once the changes are complete and tested, they can be merged into the main branch.

GitHub makes version control even more useful by providing an online platform where teams can store and manage their Git repositories. It allows multiple developers to collaborate on the same project from different locations. Team members can upload their work, review each other's code, and discuss improvements before changes are added to the main project. This helps improve the quality of the project while reducing mistakes.

Another advantage of GitHub is that it keeps a complete history of every change. Users can see who made a change, when it was made, and why it was necessary. This makes it easier to identify problems, fix bugs, and understand the development process. GitHub also supports pull requests, code reviews, and issue tracking, which help teams organize tasks and maintain good communication.

Overall, Git and GitHub are essential tools for cloud projects because they make teamwork easier, improve project organization, and reduce the risk of errors. By tracking changes, supporting collaboration, and allowing developers to recover previous versions when needed, GitHub helps teams build and manage cloud resources more efficiently and with greater confidence.

Submission Requirements

- ✓ GitHub repository created
- ✓ README.md completed
- ✓ Reflection paper added
- ✓ Repository folders organized
- ✓ Markdown displays correctly on GitHub
- ✓ GitHub repository link submitted

Repository Link: <https://github.com/Aikai25/CCM-101-Cloud-Computing.git>
